

ProtectIt 5.0

Getting Started with ProtectIt

ProtectIt 5.0 allows you to password protect pages.

- Run the Installation program, specifying the location of Fusion 4.0/5.0's component directory.
- Launch Fusion
- If the coolmaps.com component toolbar is not visible choose View > Toolbars > Component Tools > coolmaps.com components
- Select the ProtectIt component and drag out an area on the page (this graphic does not appear on the published page).
- NB: Only place the ProtectIt component in the Layout area of the page you wish to protect, not the Masterborder.

The ProtectIt properties now appears in Fusion's properties palette.

ProtectIt is a two part component. Once you have configured the options in the Properties Palette, you must enable the Post Publish ProtectIt component (Choose Publish View > Publish > Publish Components)

ProtectIt Options

Number of Passwords

Choose the number of unique passwords you would like to have. (You may have up to 20 passwords.) This will open up the same number of boxes for you to enter the passwords.

Password #X

Enter the password - we would recommend no spaces or non-english characters in the password. Also note that the password is case sensitive.

Password Prompt

Enter the text that you would like to appear to prompt the user for the password. (Do not use quotation marks or other "non-javascript-friendly" characters in the text.)

Error Page

Select a page that will be displayed if the visitor enters an incorrect password.

Create Index Page

If your server allows users to browse directories, this option enables you to create an index page (the page that shows up when a url contains just a directory - no file). Usually this page is named index.html (the default). So, by creating an index.html page, you can make it so that no one will be able to browse your directory. And, if no one can browse your directory, they will not be able to know the filenames contained within.

Index Page Name

If "Create Index Page" is selected, this option lets you override the default index.html name with the name that is specific to your server.

Once the Palette options are configured the Post Publish ProtectIt component must be enabled.

- Choose Publish View > Publish > Publish Components
- Check the ProtectIt option.
